THE ORDER OF SCIENTIFIC MERIT AND THE VALIDITY OF VOTES¹

IN selecting groups of one thousand American men of science for statistical study in 1903 and 1909, the workers in each of twelve sciences were arranged in the order of merit for their work by ten of their leading colleagues.² The average positions gave the order, and, as there were ten observations of the position of each individual, its probable error could be calculated.

As the writer of this paper is a psychologist and the ultimate object of the work is the study of behavior with a view to advancing scientific research, the psychologists may be used for illustrations of method. William James was placed first in 1903 by the independent judgment of each of the ten observers. The psychologist who stood second had an average position of 3.7 with a probable error of 0.5; the chances are even that his position was between 3.2 and 4.2. The psychologists who stood third, fourth and fifth were assigned, respectively, positions of 4.0, 4.4 and 7.5, with probable errors of 0.5, 0.6 and 1.0. It follows that the relative order of Nos. II, III and IV is not determined definitely, whereas the chances are some 10,000 to 1 that each of these stood below No. I and above No. V. The probable errors increase in size as the work of the men becomes less significant; it is on the average 0.65 places for the first ten of the fifty psychologists and 10.7 places for the last ten. Consequently No. XL on the list would have about one chance in four of falling out of the group of fifty, if the number participating in the arrangement had been very large.

The figures determine not only the validity of the positions, but also the differences in scientific merit among the psychologists, these varying inversely as the probable errors. As men who are about 6 ft. 2 in. tall are likely to differ from each other about ten times as much as

men who are about 5 ft. 8 in. tall, so the more distinguished scientific men at the top of the list differ from each other about ten times as much as those toward the bottom, and a unit can be adopted for measuring the differences. This method for converting relative positions into degrees of quantitative differences, which was first used by the writer³ to measure subjective differences in the intensity of lights, has proved to be of wide application.

For a third selection of our thousand leading men of science it seemed desirable, in order to avoid the inbreeding that might occur through selection by a limited group, to obtain a general vote from those competent, and, as before, the new methodological problems have proved to be of interest. The validity of votes appears not to have been considered, yet the problem is wide-reaching and is closely related to the drawing of balls from an urn, which has largely occupied students of the theory of probabilities.

If, for example, the council of the American Psychological Association, which consists of eight members, decides without consultation in favor of a given measure by a vote of 6 to 2, how likely is this to represent the majority opinion of the 432 members? We do not know the distribution of this "population," but if from an urn containing 216 white and 216 black balls 8 are drawn, the chances are about one in nine that 6 will be white and about one in seven that 6 or more will be white. These may be regarded as approximately the chances that when the membership is about evenly divided a vote of that character will be obtained from the council; and on this basis the desirability of a plebiscite vote may be decided.

In 1916 Mr. Wilson was elected president by the vote in California, which was in his favor

by 466,300 to 462,394, giving him a majority of 3,906. It might be supposed that this small majority would readily have been reversed by an indefinitely large electorate, but if the population were equally divided this would probably occur only once if an election were held every day for a hundred years.

If the members of a jury reached their decision without consultation and stood eleven to one for conviction, many would conclude that the chances are eleven to one that the defendant is guilty. As a matter of fact if the total population is divided in the same ratio and the legal fiction is followed that a man is proved guilty or innocent only by unanimous vote of twelve peers, the chance of obtaining a jury which without consultation will be unanimous for conviction are about one in three, of obtaining a jury unanimous for acquittal, only one in many billions. The practise of the courts must ultimately adjust itself to such conditions, and learn whether the unanimous vote of three or five jurymen without consultation is more or less valid than the unanimous vote of twelve after consultation. It must be decided on what probabilities a man shall be convicted and to what extent the chances of innocence shall be considered in imposing sentence.

When our rulers are selected and their legislation is determined by votes, it seems strange that knowledge concerning the variable and constant errors is so completely lacking. A decision of the supreme court, which may involve the welfare of hundreds of thousands of children or taxation amounting to billions of dollars, is equally binding whether the vote is unanimous or by a majority of one. It would apparently be as reasonable to require a three fourths vote of the supreme court to invalidate a law passed by both houses of the congress and signed by the president, as to require a unanimous vote of a jury to award petty damages.

The method of voting used to select scientific men might have useful applications in industry. For example, if a bank employs 100 clerks, some of whom will be promoted from time to time, all of them might be asked to check the fifty per cent. and the five per cent. most deserving of promotion. From the records an order of merit for promotion would be obtained, together with the relative value of the men to

the bank and the salaries deserved. The data would also throw light on those voting, for the value of the judgment of each is measured by its departure from the average; if any were prejudiced or unfair in their treatment of friends or rivals this would be discovered. The combined judgment of associates is probably a more valid method of selection than the choice of a superior and would presumably lead to better service.

In like manner a group of factory workers or of laboring men might select a boss or leader by vote. If the employer would agree to take one of the five men receiving the most votes, the employees would understand and probably approve the method. Not only would a good selection free from favoritism be made, but the men would share in the control of their work and would be more loyal and more efficient.

The writer has proposed a compromise between the competitive and the semi-communistic systems for payment of the salaries of university professors, according to which, say, five super-professorships with relatively large salaries and large freedom should be established. The difficulty under our present method is that the appointments would be by favor of the administration. If, however, a vote of the teachers in the university, and perhaps of the students, were taken on the basis of desert for research, teaching and service, a method of selection would be used probably more accurate than the choice of the president and at the same time more conducive to cooperation and goodwill.

In the selection by votes of one thousand scientific men the same number for each of the twelve sciences was retained as in the two previous studies, this being nearly proportional to the total number of workers in each science. In the first edition of "American Men of Science" there were listed about 4,000 scientific men, in the second edition about 5,500, and in the present edition, published some fifteen years after the first, the number is about 9,600. The present writer was in 1888 the only professor of psychology in the world. The number of members of the American Psychological Association, which has a professional qualification, increased from 127 in 1903, when the first selection was made, to 432 in 1920. The average number of doctorates conferred in psychology during the

THE DISTRIBUTION OF VOTES FOR ONE HUNDRED PSYCHOLOGISTS

five years prior to 1903 was 12.6; it was 40 in 1920. Competition for inclusion among our fifty leading psychologists or among our thousand leading men of science is thus much more severe at present than was the case when the selections were first made. There are now about 500 working psychologists and about 10,000 scientific men in the United States; the present selection consists approximately of those who form in each science the upper tenth in merit of their work.

In the case of the psychologists, here used as an example, those in the two earlier groups of fifty (except five no longer occupied with psychology or no longer residents of the United States), numbering 48, were asked to send the names of 10 or a smaller number of others whose work warranted their inclusion in such a group. Then those who received two or more nominations were in like manner asked to propose 10 or fewer names. The 52 who received the most votes were added to the original 48 to form a group of 100. These names were placed

in alphabetical order on a list, which was sent to them all, with the request to "check (✓) about 50 (namely, about one half) of the names to indicate those who have done the best work in psychology, placing a double check (✓✓) before about five of those whose work has been the most important." Eighty-three (besides one who replied too late) of the 100 returned the blank and, as each was asked not to consider himself, there were 82 votes. When more than five double checks were assigned they were weighted inversely as the number. The result of the votes can be conveniently shown by curves such as are here reproduced. The middle curve gives the distribution of the 82 votes for the 100 psychologists, the vertical ordinates representing the number of votes, while the individuals are ranged serially along the horizontal axis. The bottom curve shows the number of double checks for each individual, namely, the opinion that he is one of the five psychologists whose work is the most important. The top curve represents the sum of two votes, and

the individuals are arranged in order in accordance with this vote.⁴

As indicated on the curve and shown on the tables (which it seems unnecessary in this place to print) two and only two psychologists were included among the fifty leading psychologists by unanimous vote of their eighty-two colleagues. The psychologist at the bottom of the fifty received 35 votes; three were given for the psychologist who stands last in the hundred. Sixty-two of the 82 voting include among the five whose work has been most important the two psychologists who received a unanimous vote for inclusion among the fifty and 20 do not. Such differences in judgment are legitimate and significant. Thus the psychologist placed eleventh is held by 22 of his colleagues to belong to the first five and by 21 not to belong to the group of 50, and similar conditions obtained for the one placed twentieth. The names could be guessed by one familiar with the situation. They are men of distinction whose more important work is by some judged not to fall within the field of psychology.

The attitude of those voting is of scientific significance, for it measures the validity of judgments. If we assume the average judgment of the 82 psychologists to be nearly correct, the departure from this average measures the competence of the individuals to form such judgments. There do not appear to be group dif-

ferences dependent on distinction or age, but individuals, as shown in the previous study, differ in the ratio of about two to one. There will be an extraordinary change in our attitude toward political, social and business problems when we learn to look upon our observations, recollections, beliefs and judgments objectively, measuring the probability of their correctness and assigning probable errors to them.

The top curve represents the sum of the two votes and the order there given is the one used. A different weighting of the two votes would not considerably affect the order. The vote for the five leading psychologists in the main discriminates only the positions of the men in the upper quartile. In place of the double vote for the five and the fifty per cent. of the 100 psychologists whose work has the most merit, a satisfactory distribution might be obtained by a vote for 25, or one fourth of the whole number. In view of the constant use of votes for elections and decisions, the problems involved deserve more complete investigation.

A probable error can be found for the positions of the individuals by a method that was apparently first used by the present writer. When eighty of those voting are divided into ten groups of eight each, we have the separate votes of each of these groups and from their variation the probable error of the average vote can be calculated. Thus the psychologist No. 1, in the ten groups of eight votes each received, respectively, 4, 4, 2, 1, 4, 7, 4, 3, 2, and 2 votes. The probable error is 0.363, and for the group of eighty votes it is 3.63. The position on the curve assigned by each of the small groups can also be found and a probable error calculated from these ten positions.

The probable errors based on 80 votes (as a rule for each fifth individual) are indicated by the broken vertical line on the curve and when referred to the order of merit by the broken horizontal lines. The probable errors of the votes of the five psychologists last in the fifty are, respectively, 3.4, 2.8, 2.8, 3.1 and 3.6, an average of 3.14. The curve from No. X to No. C is nearly a straight line, the vote decreasing from 79 for No. X to 3 for No. C. Consequently the probable error of the vote when referred to the order is increased by about one sixth. The probable error of position at the

⁴ Similar results have been obtained in each of the twelve sciences, the number of scientific men ranging from 175 chemists to 20 anthropologists. The returns, however, were most complete for psychology, the writer being personally acquainted with nearly all psychologists and a second request having been sent to those who did not reply to the first. There were in all some 130,000 votes to be collected, counted and tabulated. For the treatment of this material I am mainly indebted to my daughter, Miss Psyche Cattell. Dr. Dean R. Brimhall and Dr. Alexander Weinstein have also assisted in the revision of the material and in the computations.

I am under very great obligations to Professor Raymond L. Pearl, of the Johns Hopkins University, and to Professor H. L. Rietz, of the State University of Iowa, for their kindness in reading the manuscript of the paper and for the useful suggestions that they have made. This acknowledgement should not, of course, be construed as involving responsibility on their part.

bottom of the group of fifty is 3.6; there are thus only three or four for whom there would be as much as one chance in four of being dropped from the list if the arrangement were made by an indefinitely large electorate of the same character.

In the first study of the psychologists, the probable error at the lower end of the fifty was 10.7, that is, there were 10 or 11 for whom there was one chance in four that they should not be included on the list. There were then ten arrangements in order of merit; now there are eighty votes. The probable error decreases as the square root of the number of observations, and the probable errors in the two cases, other things being equal, should be about as 3:1, which is in fact almost exactly the case. The probable error of a single vote for the psychologists low in the group of fifty at the present time is thus the same as by order of merit in the group of 1903.

In the first study, however, we were concerned with the upper quartile, and we are now concerned with the upper decile of the group of American psychologists. If we assume distributions in accordance with the curve of error, the men who now stand at the bottom of the fifty in the present selection will be as able as those who stood about twenty in the first arrangement. An examination of the relative positions of the individuals who are in each of the two arrangements indicates that this tends to be the case. The probable error at the bottom of the fifty selected by votes should be in the neighborhood of those who stood about twenty in the first arrangements. This would make a single vote one half as valid (the ratio of the probable errors in the first arrangement for those near the bottom of the fourth hundred and in the tenth hundred of the thousand being 64:125) as a single judgment of order of merit. The figures given should, however, be regarded as indications of method rather than as exact determinations, for they are subject to various errors.

The average position of the survivors of the first group of psychologists in the arrangement of 1903 was (after deaths have been eliminated) 4; it is now for the same individuals 14.8. Those in the four following groups of ten have dropped, respectively, from 11.5 to 18.1; 20 to 27.4; 29.5 to 59.2, and 39.5 to 64.9. This drop

in position is on the average less than would be expected if the 10,000 scientific men of to-day are as able and have as good opportunity as the 4,000 scientific men of 1903. The inference is that as the total number increases the proportion of men of distinction decreases. This may be due to the fact that men of special ability find their level apart from the size of the group or because the scientific career attracts less able men or gives them less opportunity than formerly. Both factors are probably present; it is apparent that the situation deserves further investigation. In the previous study it was shown that in the increased competition of a five-year period, those between 40 and 44 years of age remained on the average about stationary; those below 40 gained; those above 44 lost, the loss being in direct proportion to the age.

As the work of the men becomes more important, the differences between the individuals as measured by the probable error of position become greater, the distribution corresponding in a general way to the upper end of the curve of error. In the case of the votes there are complications, for the votes for different men do not have the same weight. The ten who receive the most votes receive nearly all the votes, and in the cases of the few who do not vote for them poor judgment or an error in checking is indicated. Some votes mean that a psychologist stands first or near the top of the list, whereas others mean that he is barely included. Consequently the order and the probable errors in the case of such a vote for one half of the group do not have great validity for the upper part of the distribution. The order is obtained in a satisfactory manner by the double vote, but this introduces further complications in the probable error. In all cases of votes, we have asymmetrical distributions and skew curves. The quantitative relations should be worked out in the first instance for less complicated material than that with which we are here concerned.

In nearly all cases in which probable errors have been applied to psychological data, the determinations are more exact than common sense would presuppose. Thus the writer found⁵ that in grading traits of character by ten individuals on a scale of 100, a position was

⁵ Address of the president of the American Society of Naturalists, *Science*, April 10, 1903.

assigned with probable errors varying from 4.6 for physical health and cheerfulness to 3 for originality and efficiency. All other traits, such as energy, courage, judgment and integrity, were assigned positions with intermediate probable errors, the average being 4, which is nearly the same as the probable error of position as determined by 80 votes of the psychologists near the middle of the 100 in order of merit.

The comparatively small probable errors appear to be due to the fact that there are constant errors which affect the whole group. The psychologists who vote are subject to the same kind of influences, not making in fact independent judgments, but being influenced as a group by the knowledge of what others think and by all sorts of conditions, conventions and restrictions. If a similar vote were taken ten years hence the work of the same psychologists would be viewed from new standpoints and the positions would change to a much greater degree than the probable errors warrant. "Constant" errors are in fact more inconstant and variable than "variable" errors.

In the case of a vote (as in any series of measurements) there are two factors entering into the probable error, one dependent on the quantitative conditions prescribed in advance, the other on the behavior of the individuals. The former may be called the deductive probable error and when the latter is determined by experiment and added to it the whole is the inductive or actual probable error. Thus, if from an indefinitely large number of balls equally distributed between black and white some are drawn, the most frequent distribution will be an equal number of black and white, but the average departure from equality will increase as the square root of the number drawn and the ratio of departure from equality will decrease as the square root of the number.

If large numbers of white and black balls are distributed in the ratio of 33 white to 47 black, and we draw 80 balls, the most probable number of white balls will be 33. The standard deviation from 33 in a large number of draws will be 4.40, and the quartile deviation or probable error will be 2.97; that is, in one case out of four there will be more than three white balls. The psychologist at the bottom of the fifty received 33 votes out of a possible 80. If

an indefinitely large number of psychologists were distributed in this ratio the deductive probable error or error of sampling would be 2.97. The actual probable error, namely, 3.63, is composed of (the square root of the sum of the squares of the two) this deductive probable error and an error or deviation due to the groupings of the psychologists into different "species" with different points of view. The psychologist who stood XIL had a probable error of 3.1. The deductive probable errors are approximately the same for the two individuals, but it is more difficult to form a judgment regarding No. I than regarding No. XIL.⁶

The situation may be illustrated by an instance of general importance. Death rates, birth rates and marriage rates are continually used, but always without probable errors. Thus, for example, the Bureau of the Census issues weekly a bulletin that contains the death rates of the leading cities of the United States, but the figures have no meaning because one does not know whether the different rates are due to chance fluctuations with a limited population or to causes such as a large proportion of infants or an epidemic of influenza.⁷ If the average death rate is 12 per thousand, in a city of 100,000 population there will be about 23 deaths in a week. If black and white balls in indefinitely large numbers are distributed in the ratio of 23 black to 99,977 white and 100,000 are drawn, the most probable number of black balls is 23, but one time in four there will be more than 27. Thus the recorded death rate for a week for a city of 100,000 will normally fluctuate. If it is on the average 12, it will in half the weeks be approximately either as large as 15 or as small as 9.

⁶In these cases the actual and the deductive probable errors have probable errors of the order of magnitude of the differences between them, and these differences have only moderate validity. The writer has purposely "not minded his p's and his q's," for it seems that equations are not becoming to one who is not a mathematician.

⁷In the last report received (for the week ending September 2, 1922) the death rate of New Haven is given as 5.8 and of Houston as 13.9. In the same week a year ago the death rate of New Haven was 10 and of Houston 7.6. Without probable errors these figures give no useful information in regard to the conditions in the two cities.

If the death rate exceeds 15 in two consecutive weeks then the chances are fifteen out of sixteen that it is due to some cause such as an epidemic. The conditions are obviously of practical importance for physicians and health officers. The situation for death rates is nicely illustrated by the illustration that has been used of the distribution of black and white balls in an urn. If the population of the country were 100,000,000 and the death rate were 12 (as it should be, but is not), then 1,200,000 people would die during a year. Among 100,000,000 black and white balls there are 1,200,000 black. But if we draw 100,000 (*i.e.*, take a town of that population) there will be a chance fluctuation as described above. It is also the case that the balls are not completely mixed, there being more black balls in some part of the urn than others. In some places we shall draw a larger proportion of black balls. When there is a negro population or a tenement house population or a large population of very young or very old people, there are relatively more black balls. There are temporarily more black balls

in one place when there is an epidemic or the like. In that case we have the analogy of the black balls attracting one another.

This paper has been written to explain the methods used to select the thousand leading American men of science by votes. The psychologists have been taken as an example; if space and time permitted tables and curves might be given for the other sciences and a study of the data might yield results of interest. Such treatment must, however, be postponed or left to others. The object of the present paper will be accomplished if it makes clear that the scientific men have been selected and placed in the order of merit for their work by valid objective methods and that the methods used have wide application. In a subsequent paper the distribution of the scientific men will be considered with special reference to the changes that have occurred in the course of ten years.

THE DISTRIBUTION OF AMERICAN MEN OF SCIENCE IN 1927

IN the fourth edition of the Biographical Directory of American Men of Science it seems desirable to add stars to the subjects of research of those who since the publication of the third edition have attained positions among our thousand leading men of science. A contemporary group was also wanted for studies of changes in distribution which make possible the measurement of movements in the history of science. It may be that in the future the development of science and the economic and social changes caused by it will be seen to be more important for civilization than any political or military event.

A determination of those who should be added to the list of our thousand leading men of science was consequently made in 1926. The 250 scientific men who had the greatest claim to be included among those previously selected were found and arranged in the order of merit. The methods of selection were similar to those used in the third edition, but were simplified by not undertaking to find the positions of the new names among the old or to determine those of the earlier group who in the competition would be dropped from it.

The simpler method was used mainly for economy, including the saving of the time of the large number of scientific men who have assisted. It is further the case that the selections can be made more accurately when only the new names are considered. It is easier to decide which 25 botanists among 50 have done the best work than to make the selection of 100 from 200. The former group is not only smaller, but also more homogeneous in age and performance.

The drawbacks of the simpler method are that it does not give us a contemporary list of the thousand leading men of science and makes only an approximation to the numbers that should be added in each science. It is, however, equally correct in so far as the stars in the book are concerned, for these indicate all those who have been included in the groups of a thousand in the four selections covering a period

of 23 years. It has frequently been suggested that the stars should be removed in the case of those who do not maintain their positions. This would be scientifically correct, but needlessly invidious, as would be dropping from the membership of the National Academy of Sciences those who have not maintained their positions among our 250 leaders in science.

The names of those added, each of whom is probably among the thousand leading scientific men of the United States, are distributed among the sciences in accordance with the numbers found in 1903 as roughly proportional to the total numbers of those who had published research work in each science. The proportions were only approximate and there have been changes in the activity of the different sciences in the course of the past 23 years, so certain sciences are over or under represented. A more exact distribution could now be obtained by classifying the some 13,500 entries in the fourth edition of the Biographical Directory, but these were not ready when the selections were made, and for purposes of comparison it is better to retain in each science the same numbers as in the preceding studies. It may be that there should be more or fewer than 100 botanists among our thousand leading men of science, but the 100 botanists are those who are regarded as having done the best work in that science by the most expert contemporary judgment.

It is arbitrary to divide the whole range of science into twelve separate sciences. For example, anatomy, physiology, pathology and zoology might be combined into animal biology, or zoology might be divided into entomology, ornithology, parasitology, embryology, cytology, animal genetics, animal ecology, systematic zoology, animal behavior, etc. The separation of the sciences is conventional, each representing the subjects that can be mastered by an individual and in which there are groups of workers concerned with related problems. The number of sciences increases continually with the progress of science; the most fruitful fields

for research are those in which two or more of the traditional sciences are involved.

If many sciences had been taken in this classification, then there would have been much overlapping, if but few, then scientific men would not have been acquainted with the whole field. In the present study the applied sciences of medicine, engineering, agriculture and education, as such, are not included, nor are the historical, social, political and philological sciences. Geography, mineralogy, geophysics and pharmacology have no separate places, apart from geology, physics, chemistry and physiology; workers in these sciences are discriminated against. It should be remembered that Canadians, though included in the Biographical Directory, are not considered in the selection, unless they were at the time residents of the United States.

In July, 1926, a memorandum similar to the following was sent to those (with the exceptions noted) in each science who had received a place in any one of the three preceding selections. Each scientific man was asked to nominate one fifth (or fewer) of the number included in the thousand in that science. Then each of those who received two or more votes was asked to make similar nominations. The memorandum for botany reads:

MEMORANDUM

For designation in the fourth edition of the Biographical Directory of American Men of Science it is necessary to obtain the names of those who should now be included among our hundred leading botanists and thousand leading men of science. The selection can be made most accurately and objectively by those included in this group in the previous editions and it is hoped that all or most of them will assist.

Will you therefore send the names of twenty or a smaller number of botanists who should probably be added? It is expected that a certain preference shall be given to those who are working in lines similar to your own, or with whom you have been personally associated. From all lists it will be possible to obtain an objective selection of those whose subjects of research should be starred in the new edition of the book.

There may be room for question as to the desirability of such a list, but the preponderance of argument appears to be in its favor. If it is prepared, this should be done with the greatest possible care, for it is a matter of importance to those

concerned. The list will also be used for further statistical studies of the distribution and work of scientific men, which was the original object of the selection.

There is enclosed a list of those included in the three previous arrangements beginning in 1902, with the exception of those who have died and several no longer active. The names and addresses are wanted of twenty other men and women living in the United States who are of nearly the same rank in their contributions to science. The individual lists will be regarded as strictly confidential.

The names with the addresses of those who received the most votes in each science were then arranged in alphabetical order, the number taken being twice as many as would be added to the thousand. Thus, for example, there are 100 botanists in the thousand and 25 were to be added. There were 334 botanists nominated and the 50 who received the largest number of independent nominations were placed with their addresses in alphabetical order on the list. This was then sent to botanists included in the previous thousands and to the fifty new names on the list with the following memorandum:

MEMORANDUM

The fifty botanists on this list are those who have received the most votes for inclusion among the hundred leading botanists and the thousand leading men of science of the United States whose subjects of research will be indicated by an asterisk in the fourth edition of the Biographical Directory of American Men of Science. In order that there may be a final and authoritative vote, please be so kind as to check (✓) the names of about twenty-five of those whose work in botany has been of the greatest value and return the list to J. McKeen Cattell, 3939 Grand Central Terminal, New York, N. Y.

designated and be included among the thousand leading scientific men of the United States. The 2,065 asked to make nominations consisted of 1,058 scientific men from the previous lists of a thousand and 1,007 who received two or more votes. A reply from two thirds of those addressed is satisfactory. It is unlikely that any scientific men who should be considered would not be proposed under these conditions, and any bad judgment, prejudice or favoritism is self-eliminating.

There were in all 2,201 nominations for the 250 places. Those asked to vote in the selection numbered 1,572, which included 1,072 on the previous lists of 1,000 and the five hundred nominees who received the most votes. The ballot was returned by 1,196 with the distribution among the sciences shown in the table. The last three columns give for each science the largest vote cast for an individual, the vote that just selected for inclusion in the 250 and the vote for the individual who received the fewest votes.

Thus, for example, the memorandum was sent to 154 botanists and was returned by 134; 98 votes were cast for the botanist who received the most, 29 for the one who received the fewest. The botanist who stood lowest among those included received 53 votes, the one next following 51. It is possible by methods previously proposed to calculate the probable errors of

these numbers. The calculations have not been made again as the earlier work applies approximately to this case. It seems that time is often wasted in calculating probable errors and correlations by the method of least squares when only an approximation is wanted. The distributions are such as to make the methods inexact and constant errors are much larger and more disturbing than the variable error. The probable error of position of the botanists at the bottom of the list of those included in the 25 selected is about three places and there are four botanists not on the list who would have as much as one chance in four of being included among our leading 100 botanists and 1,000 leading men of science if the electorate had been indefinitely large. They would, however, have had positions near the bottom of the list.

The methods of selection are thus accurate and the degree of accuracy can be measured. Indeed the exact determination has a certain brutality in view of the human interests involved. All those who voted have competence, though in varying degree. Thus in the first study it was found that if we assume the average result to be correct, the validity of the judgments of the different individuals varied as about 2:1. This appears to be of interest because the validity of judgments was then for the first time measured and because the range of individual differences for normal individuals

in other traits, such as time of reaction, accuracy of discrimination and correctness of memory, had been found in laboratory experiments to be about the same. There was no significant difference between the average judgments of those more or less eminent in science, nor between the older and the younger men. If what we mean by judgment could be further analyzed, differences might be found; thus the more eminent and the older groups might have had more experience but less information in regard to contemporary conditions.

A distinguished mathematician argues that his judgment has greater validity than the average of the judgments of 100 mathematicians less eminent and presumably less well informed, holding that when there is a difference of opinion he is likely to be right and the group wrong. He voted for nineteen of the forty, naming four of those not selected by the majority and failing to name five of those so selected. The chances are somewhat over 4 to 1 that if he had voted for 20, he would have voted for 80 per cent. of the selected list. This is in fact a satisfactory agreement, giving what the probable error would predict. The variable error would lead us to assume that the combined vote of 100 mathematicians would be about ten times as correct as the vote of one of them, which would be reduced to five times if his judgment were twice as accurate as the average of the other individuals. The majority might, however, be subject to a constant error sufficiently large to outweigh the variable error.

A plebiscite vote may have no validity when the voters are uninformed and are moved by mob emotions. Thus when Cook claimed that he had reached the North Pole, and Peary was supposed to have been ungentlemanly because he questioned the claim, a newspaper in the Middle West obtained a vote of its readers on the two questions: "Did Cook reach the North Pole? Did Peary reach the North Pole?" The vote that Cook did reach the Pole was overwhelming and a smaller majority voted that Peary did not. It would not be feasible to determine whether man has descended from a lower order of animals by a popular vote in Kentucky. But it is also undesirable to leave the decision of every question to a Lenin or a Mussolini. The conditions are best when a

democracy is sufficiently intelligent to choose its experts. It is the business of science to determine the validity of votes, judgments and decisions, a difficult task, but not more so than other problems of lesser human consequence which it has solved.

The 250 new names added in 1927 to the thousand of 1921 are about the number that would have won places to fill vacancies caused by deaths, to meet variation due to the probable error of selection, and as a result of competition with those on the list. There were on the list of 1910, 269 new names; on the list of 1921 (the interval having been prolonged by the war), 351 new names. The residences and positions of the scientific men are of January 1, 1906, 1910, 1921 and 1927. There is of course an interval between the time at which the selection of the names is begun and the completion of the final result. In the first arrangement this interval was about three years; in the last it has been reduced to five months. A statistical study of the names added in 1921 (whose subjects of research are prefixed by a star in the 1921 edition of the Biographical Directory) was made with the assistance of Miss (now Dr.) Psyche Cattell, Dr. Dean R. Brimhall and Dr. Alexander Weinstein, but the work was not published. The 351 names selected in 1920 and the 250 selected during the latter half of 1926 have now been combined and the 601 scientific men (with the residences and positions of January 1, 1927) are treated in the present study and compared with the list of 1906. In this compilation Jaques Cattell and Mrs. Quinta Cattell Kessel have assisted.

The increase since 1906 in the number of scientific men who have contributed by research to the advancement of science is notable. According to the sketches in the Biographical Directory there were about 4,000 in 1906, about 5,500 in 1910, about 9,500 in 1921, about 13,500 in 1927. The names may have been more completely selected in later editions, but this is perhaps counterbalanced by the greater difficulty in dealing with the larger numbers.

The question as to whether contributions to science, including notable advances, are increasing as rapidly as the number of scientific men is of fundamental importance. It appears that while scientific publication increases in

proportion to the number of workers, the number of great men of science and of notable contributions does not so increase, if indeed there are as many such men and as many such contributions as there were 25 or 50 years ago. There are more than ten times as many scientific men as when Joseph Henry, Louis Agassiz and Willard Gibbs lived. We do not have thirty men so distinguished; do we have three? Are there ten contributions or is there one, to be later recognized, as in the case of the work of Willard Gibbs?

Among those high on the list of 1906 who are no longer living are: *Astronomy*, Simon Newcomb, G. W. Hill and E. C. Pickering; *Physics and invention*, S. P. Langley and A. Graham Bell; *Chemistry*, Ira Remsen, E. W. Morley, O. W. Gibbs and J. W. Mallett; *Geology*, G. K. Gilbert, C. R. Van Hise and Charles D. Walcott; *Botany*, W. G. Farlow; *Zoology*, W. K. Brooks, C. O. Whitman and Alexander Agassiz; *Physiology*, H. P. Bowditch, S. J. Meltzer and Jacques Loeb; *Anatomy*, Charles S. Minot and F. P. Mall; *Pathology and medicine*, William Osler; *Psychology*, William James. There are men of science now living who in 1906 stood equally high. The question is whether in this period there have arisen men to replace those who were then the leaders. We do not have three times as many, although the supply of scientific men is more than three times as great. Probably in some sciences we have now men of as high distinction as we had 21 years ago, in others not; in none do we seem to surpass obviously the earlier period. It appears that the situation is similar in England, Germany and France.

In Table II there is shown by states the birth place and residence of the 601 scientific men of the lists of 1921 and 1927. In their production New York leads with 67, followed by Ohio with 49, Massachusetts with 48, Illinois with 45, and Pennsylvania with 41. The group of states next following consists of Iowa 27, Wisconsin 24, Missouri 21. The position of the North Central States is noteworthy, and is further emphasized by the situation in states having a productivity between 10 and 20, namely, Indiana 18, Connecticut 16, Minnesota 14, Maryland 13, Michigan 13, California 11, Kansas 11. ing from the South Atlantic, South Central and Western divisions is small, though there has been some gain since 1903.

Of the leading thousand scientific men selected in 1903, Massachusetts produced 134 and Connecticut 40. At the time of their birth Boston was the intellectual center of the country. New York in proportion to its population had then produced about half as many scientific men as Massachusetts and Connecticut, the North Central States about one third as many. The situation had changed for the list of 1910. Reduced to comparable figures the birth rate of leading scientific men per million of population had fallen in Massachusetts from 109 to 85, in Connecticut from 87 to 57. In Michigan it had increased from 37 to 74, in Minnesota from 23 to 59, in Wisconsin from 45 to 54. The intellectual fecundity of the North Central States, as compared with New England, has now further increased, extending westward and southward to Iowa, Missouri and Kansas.

The situation is shown in the table by increasing the 601 scientific men to 1,000 proportion-

ately distributed, which is approximately the result that would have been obtained if 1,000 had been selected. Under these conditions the gains or losses of each state are given. The situation in New England is ominous for the future. Every state has lost and it appears that the rural population is becoming intellectually sterile. Of the thousand leading scientific men in 1903, Maine had produced 29, of whom 19 ranked in the first 500. Of 601 scientific men mostly born less than 50 years ago, the state has produced six; if a thousand had been selected the most probable number would have been ten. It has consequently lost 19, two thirds of its productivity. Massachusetts has lost 54. Analogous conditions obtain in all the New England States and southward along the Atlantic. The losses of New York, New Jersey and Maryland, in spite of, or it may be because of, their enormous increase in wealth, are startling. Pennsylvania and Delaware remain nearly stationary; there are small gains in most of the South Atlantic and South Central States.

The losses of the eastern states are counterbalanced by the gains of the central states, notably Illinois, Minnesota, Iowa, Missouri, Kansas and Nebraska. All the central states have gained except Michigan, though the gains in Ohio and Indiana are small. These three are the most eastern of the states and appear to be following in the wake of the Atlantic seaboard. Further to the west there tend to be moderate gains which predict a large future development. So indeed westward does the course of science take its way, but it is not gratifying if the eastern states do not equal the cultural nations of Europe before losing their leadership. This may indicate a waning of the world's great era in science.

Ten of the scientific men on the list of 1921 have died, giving an annual death rate of 4.7 per thousand which is about normal for men of that age. Of the 591 remaining on the two lists, 122 live in New York, 57 in Massachusetts, 52 in Illinois and 47 in California. If the numbers are increased to 1,000 and proportionately distributed, it appears that in comparison with the thousand of 1906 Massachusetts has lost 49, whereas Illinois has gained 24 and California 23. Every New England state,

as also New Jersey, Maryland, Virginia and North Carolina, have a smaller proportion of these leading scientific men than they had 21 years ago. New York has gained 11; Pennsylvania has lost two. Next to Illinois and California, Minnesota has the largest gain. The smaller gains or losses in other states show the real situation at the time and are significant, especially in view of the grouping by regions.

When we compare the birthplaces and residences we find that New York has acquired 55 more of the scientific men than it has produced, the individuals of course not always being the same. Massachusetts has gained 9, Connecticut 4, New Jersey 10 and Maryland 10, these representing men called to the universities. Illinois for the same reason has gained 7, Michigan 5 and Minnesota 4. In the other central states the loss has been large. One hundred and sixty, more than one fourth, of the scientific men were born in them and only 55 reside there. There are but few scientific men born in Washington while many are employed in that city by the government. Of the new group, three were born in the District of Columbia and 77 reside there. Eighty-six of the scientific men were born abroad, so they more than supply the excess in Washington and the balance remains nearly even for the different states.

In 1906 one half (501/1,000) of the leading scientific men of the United States resided in the North Atlantic States and somewhat more than one half (518/993) had been born there. In the short period of 26 years the proportion of those born in these states has fallen to one third (200/598) and the percentage of those residing there to 44.5 per cent. (263/591). The cities of the eastern seaboard depend in large measure on Europe for their population, on the central west for their wealth and for their leaders. They will face a difficult situation when immigration is nearly cut off and centers of wealth and culture develop toward the west. It might be supposed that as wealth increases in the hands of a plutocracy, so scientific and other culture would increase in its centers. There has obviously been no change in native ability in the course of a few years. The only suggestion here made is that the state universities and denominational colleges of the central and western states are more nearly in touch

with the people than the privately controlled universities of the east and have proved to be the better agencies for the selection and training of those having ability and ideal interests.

The eastern universities provide education for more men who become leaders in science than the states produce. As American students formerly went to Germany for advanced work, so in a later period they tended to congregate in the endowed universities of the Atlantic seaboard. The first degree of doctor of philosophy in the United States was given by Yale University in 1861, the first scientific man to receive it being Josiah Willard Gibbs in 1863. Prior to 1876, Yale had given 18 doctorates in the sciences, Harvard 4, Columbia and Cornell 2 each. Then was established the Johns Hopkins University, opening a new era of higher education and scientific research in the United States. In the following 20 years the Johns Hopkins conferred 179 doctorates in the sciences and 84 of the recipients (some had died) were on the list of 1,000 scientific men of 1910. During this period Columbia conferred 67 such degrees, Harvard 66, Yale 56, Cornell 33, Pennsylvania 22, Clark (opened in 1888) 21, Chicago (opened in 1892) 8, all other universities 66.¹

Up to and including 1910, the universities of the United States had conferred 2,513 doctorates for work in the sciences, the distribution being: Johns Hopkins 434, Chicago 276, Yale 271, Columbia 268, Harvard 267, Cornell 222, Pennsylvania 172, Clark 150, all others 453. Thus eight endowed universities awarded more than four fifths of these degrees. In 1926 according to data compiled for the National Research Council by Callie Hull and Clarence J. West there were 740 doctorates conferred in the sciences, the numbers for the leading institutions being: Chicago 78, Wisconsin 53, Johns Hopkins 50, Columbia 49, Illinois 44, Cornell 43, California 38, Yale 38, Harvard 35, Washington 32, Minnesota 30, Iowa 28, Ohio State 25. Thus Chicago in the central west is far in

¹ These statistics concerning doctorates in the sciences are from an unpublished study. From 1898 to 1915 there was printed each year in *SCIENCE* an article on doctorates conferred by American universities, including the names of the recipients and the subjects of the theses in the natural and exact sciences.

advance of the eastern privately controlled universities and the seven eastern universities which had conferred prior to 1910 nearly three quarters of all the degrees in 1926 conferred fewer than seven state universities of the north central states and California.

Table III gives the institutions from which five or more of the 601 scientific men received their degrees. Harvard with 41 bachelors, 62 doctors of philosophy and three doctors of medicine, stands foremost as it did in 1903. It is, however, now surpassed by Chicago in the number of doctorates, as it was by the Johns Hopkins at the earlier period. After these three universities comes Columbia, followed by Yale, Pennsylvania, Cornell and California. The institutions whose graduates are in the twenties are Michigan, Minnesota, Princeton and the Massachusetts Institute; ranging from 18 to 12 are Wisconsin, Stanford, Indiana, Kansas, Illinois and Ohio State. The privately endowed universities still lead in the number of

scientific men for whose education they were responsible usually some twenty to twenty-five years ago. They probably do not do so for the men graduated to-day, but we must wait another twenty years before the figures will be at hand. Many of the 41 bachelors who received degrees from Harvard and the 15 from Columbia and from Yale went to these universities from other institutions after they had planned their careers and the influence of the eastern endowed universities in the creation of scientific men is not large. The private colleges are also losing the influence that they formerly had. In the thousand of 1906 there were 23 graduates of Princeton and of Amherst, 16 of Wesleyan, 14 of Williams, 10 of Dartmouth and of Oberlin. For the contemporary list of 601 men the numbers are: Wesleyan 8, Princeton, Dartmouth and Williams 5, Amherst 4, Oberlin 2.

Another change that can not be regarded as wholly auspicious is the small number of the younger scientific men who have studied at foreign universities. In so far as this means such advance in our own institutions that it is needless to go abroad for special work it is gratifying. But it may result in lesser devotion to the ideals of scholarship and research that had their florescence in the German university of the nineteenth century. Of the thousand of 1906, 117 had studied in Berlin, 84 in Leipzig, 69 in Göttingen, 56 in Heidelberg, and a large proportion had received degrees from these and other German universities. Of the contemporary 601 only one has a degree from Berlin. There is none from Leipzig, which before had 39. This refers, of course, to men working in the period preceding the war. Perhaps now the various systems of unattached fellowships may lead to a larger international interchange of students. Before graduate students can afford to study abroad, we must, however, find a method by which younger scientific men receive positions in accordance with their ability rather than through the influence of the professors with whom they work.

The majority of scientific men still find their careers in universities. As shown in Table IV, 358.5 (the decimal here and elsewhere referring to a divided position) of the 591 men hold academic positions and in the main earn their salaries by teaching. There are 95 connected

with the research institutions that are the most notable development in scientific investigation of the present century. The Smithsonian Institution (including government bureaus), museums, etc., are here placed under research institutions. Sixty-two are engaged in industrial work, largely in the research laboratories of the corporations, where their work is not confined to applied science and will doubtless be more and more extended to the fundamental problems whose cultivation and by-products have an economic value far beyond their cost. Such work is besides only a proper return to society for the wealth acquired by monopoly. A public service corporation such as the American Telephone and Telegraph Company, whose profits are limited only by legal regulations, could easily and properly support and give the best facilities to scientific men engaged in research in physics, chemistry, mathematics and psychology. 74.5 of the men are employed by the government. Here again the work is largely but not wholly in applied science, and here again the most beneficial use of money collected by taxation would be the support of research that of all services is the most important for the nation and for the world.

Of these scientific men 60.7 per cent. hold academic positions as compared with 73.8 per cent. of those in the list of 1910. It has been recognized that there has been since the war a movement of scientific men from the universities to the research and industrial laboratories

and we have here a measure of its extent. If the numbers are, as above explained, increased to a thousand we find that of this younger group the universities and colleges have lost 133. The research institutions have gained 88.5; the industrial laboratories and applied science 46; the government services 14.5. There is only one who may be classed as an amateur in the present list, as compared with 18 in 1910. We have never had in America a group of men, such as was represented in England by Darwin, Galton, Rayleigh and Huggins, who devoted themselves to scientific work without occupying scientific positions. The specialization of science and democratic institutions have led to the practical disappearance of those who contribute significantly to the advancement of science without being professionally engaged in scientific or educational work. But we now have men who are professionally engaged in research.

The figures for the separate sciences given in the table show that nearly all mathematicians are teachers. Astronomy and pathology are especially well represented in the research institutions; geology and to a lesser extent physics, botany and zoology in the government work; physics and chemistry in the industrial laboratories and in applied science.

Table V gives the number of scientific men connected with institutions where there are three or more. As we are here in the main concerned with the present strength of the institutions rather than with changes in distribution all the scientific men are included. They are divided in the table into three groups: (1) the scientific men of the list of 1910 who were retained in the list of 1921; (2) those added in 1921; and (3) those now added to the list. The numbers in the three groups, respectively, are 585, 341 and 250. We have consequently 1,176 scientific men instead of 1,000 as in the earlier lists. The competition for inclusion is now, however, more severe, for the list of 1906 included about one fourth of the scientific men of the country, whereas the present list includes only about one twelfth. The figures given in the table are consequently relative. An increase of 17.6 per cent. means that an institution has remained stationary in its relation to other institutions.

Harvard has on its faculties 89.5 of these leading scientific men and its supremacy is un-

challenged. Under the existing system of university administration honor should be given to Mr. Eliot and Mr. Lowell for maintaining high academic traditions. It is a remarkable circumstance that Harvard should have gained 23 scientific men of distinction during the period in which New England has been failing in the production of scientific men and the centers of scientific research have been moving westward. In 1906 Harvard had 66.5 of our thousand leading scientific men, Columbia 60, and Chicago 39. Now of 1,176 leading scientific men Harvard has 89.5, Chicago 53.5, and Columbia 46.5. It should also be noticed that Harvard has 21 of the younger men of the group of 250, as compared with 15 at Chicago and 7 at Columbia. Following these three universities are Yale with 42.5 and California and the Johns Hopkins bracketed with 40.5. Cornell, which comes next, has lost relatively. There then follow the three state universities, Michigan, Wisconsin and Illinois, of which Illinois has gained the most. Next come four endowed institutions, Stanford, Pennsylvania, Princeton and the Massachusetts Institute of Technology. Washington (St. Louis) is in the same group and has the largest gain. The only other universities having ten or more of these leading scientific men are Minnesota and the Ohio State. Apart from Columbia the universities that have lost most relatively are Missouri, Syracuse, Wesleyan, New York and Virginia.

The past twenty-six years have witnessed the development of endowed research institutions and the Carnegie Institution of Washington now stands next to Harvard and Chicago in the number of its scientific men of distinction. The Rockefeller Institute, limited to medical research, has also attained a high position. In this period the Carnegie Institution has grown from 7 to 47; the Rockefeller Institute from 3 to 19. The Boyce Thompson Institute, the Wistar Institute and the Mayo Clinic attain places on the list. The American Museum of Natural History and the New York Botanical Garden, with respectively 13 and 8 of the scientific men, rank before most universities and show a gain since 1906. It is of interest that these institutions can flourish under support and control partly private and partly public.

The industrial laboratories of the corporations, like the endowed institutions for research,

have enjoyed a notable growth which is scarcely measured by the 11 men recorded for the General Electric Company, the 10 for the Bell Laboratories and other parts of the Telephone System, and the 5 for the Eastman Kodak Company. Industrial research, like advances in engineering, is not always recorded in scientific papers, and is often a cooperative undertaking for which credit is not assigned to individuals. It is, however, to be noted that the number of leading scientific men under these three corporations has greatly increased and of 26 all but three belong to the two groups consisting mainly of younger scientific men.

The Bureau of Standards has during the period increased the number of leading scientific men in its laboratories from 8 to 22. The Geological Survey, with 28.5, is the strongest group in a single science, but relatively it has

lost ground somewhat since 1906, as has also the Department of Agriculture. The Smithsonian Institution, with its government supported subsidiaries, has remained stationary, but this means a moderate relative loss. The U. S. Public Health Service has gained and some states and municipalities are now cooperating in this work.

In Table VI the ten strongest departments in each science are given, the men in them being weighted in accordance with the methods described in the previous study. Those on the lower part of the list being taken as a unit, a scale has been adopted of increasing weights up to 4 for the 25 at the head of the list. This scale corresponds in a general way with the range of merit and the average salaries received. The 250 men added to the list have been arranged in order of merit and interpolated in

the list of 1921 in accordance with the distribution found in the previous arrangements. The probable errors of the figures given in the table, which are small, and the constant errors, which in some cases may be considerable, are discussed in the earlier publication. Owing to the possibility of injustice to certain departments there has been some hesitation as to the desirability of publishing the figures, but they are in the main correct and significant. The figures are omitted in cases where the strength of a department is less than 4 in order to avoid giving possible information in regard to the standing of individuals.

Harvard here shows its leadership not only as a whole but in nearly every department. It stands first among universities in physics, chemistry, geology, botany, zoology, physiology and pathology, second in mathematics, third in

astronomy and psychology, fourth in anthropology. There has been a gain since 1906 in every department except anatomy and psychology, though in several cases the gains are due only to the increased number of individuals on the present list. Chicago stands first in mathematics and second in zoology. Columbia stands first in psychology, but does not in any other science have a rank higher than fifth. The U. S. Bureau of Standards leads in physics and the Bureau of Entomology in anthropology. By a wide margin the Carnegie Institution leads in astronomy, the U. S. Geological Survey in geology, the U. S. Department of Agriculture in botany and the Rockefeller Institute in pathology.

THE SCIENTIFIC MEN OF THE WORLD¹

THERE has for a long time been planned a study of the scientific men of the world on the lines of the statistical work on American men of science. International directories in the several sciences were taken up, those in psychology and zoology having been partly prepared, the latter in cooperation with Professor T. D. A. Cockerell. In connection with the third edition of the Biographical Directory of American Men of Science it was proposed to select by objective methods the thousand leading scientific men of the world. With such a list it would be possible to determine among other things the value of the contributions of each country to each science, both in quantity of work accomplished and in fundamental advances.

In order to obtain preliminary data I wrote in June, 1914, to the scientific academies of different countries asking for their membership lists. These were mailed from most of the German and other academies after war had begun. It was obviously impossible to continue the work at that time; it was indeed necessary to postpone the preparation of the third edition of American Men of Science. We have scarcely yet reached a situation where international cooperation and unprejudiced judgments are feasible; but the methods used enable us to measure validity of judgments and prejudice, so that the study might at the present time be of special interest from that point of view. We could, for example, measure the normal distortion of judgment through nationality, its excessive manifestation during war and its subsequent waning.

In connection with the study begun some years ago I counted up the scientific men of different countries in "Who's Who in Science," edited by H. H. Stephenson and published in England by Churchill. There has been no edition of the book since 1914, and the figures just before the war are no longer valid, but they have sufficient interest to warrant their publication, more especially in view of the recent widely quoted remark by Secretary Hoover to the effect that the United States is behind most European

countries in its contributions to pure science and the statement of the National Research Endowment of the National Academy of Sciences to the effect that "the United States, which already occupies a leading position in industrial researches, should rank with the most enlightened nations in the advancement of pure science."

The scientific men whose biographies are included in "Who's Who in Science" and whose numbers are given in the table were probably selected somewhat at random, those of Great Britain and its colonial empire being the most completely represented and the United States coming next. Perhaps 800 from Great Britain and 1,200 from the United States would be a fairer basis for comparison with other countries than the 1,729 given from the former and the 1,845 from the latter. In that case Germany would be in the lead. The numbers from the non-English speaking nations may be regarded as comparable, though they doubtless vary with the sources of information.

If we take the figures as they stand, the United States, Great Britain and Germany were in 1914 far in advance of other nations in the numbers of their scientific men. France had 504, as compared with 1,334 from Germany; the then Austria-Hungary with 467 was nearly equal to France; Italy had 246. There then follow Switzerland with 215, Norway with 170 and Holland with 159. Sweden has 124 and Denmark 97.

According to the figures in the table referring to the several sciences, the United States stands higher in the so-called pure sciences than in medicine and engineering. We indeed stand first in all the natural and exact sciences except chemistry (largely on applied science) and geography. It is naturally gratifying to the present writer that psychology is the science in which we are most decidedly in the lead. We have 95 of the world's leading psychologists as compared with 30 in Great Britain, 37 in Germany and 12 in France. Geography is the science in which we are most deficient, 18 geographers being attributed to the United States, as

compared with 44 to Germany and 42 to Great Britain. After psychology we are strongest in zoology, botany, agriculture and geology. This is what I guessed in a preceding discussion² of the subject, but I then added astronomy to psychology, zoology, botany and geology as the subjects in which we were probably in the van. The sciences in which we make relatively the poorest showing in the table, apart from the applied sciences and geography, are anatomy and astronomy. The differences in the percentages for the different sciences are, however, not large and would probably fall within the probable errors of sampling if these could be determined.

The figures in the table relate to a period preceding 1914. They do not have great validity even for that time, and the years that have since elapsed have been significant for international changes. The edition of *American Men of Science* published in 1910 contains about 5,500 biographies of those who are supposed to have made contributions to science, the edition now in course of preparation will contain in the neighborhood of 14,000. The increase may to

some extent be due to more complete representation, but in the main it measures the increase in the number of scientific workers. They have probably about doubled since the data were compiled for "Who's Who in Science." The increase has been much less elsewhere; indeed there may have been none in some nations, such as France and Italy. With the possible exception of Germany the United States is now far in advance of every other nation in the number of its scientific men and in the number of its contributions to science.

It does not follow that the number of great men of science and the significant contributions are proportional to the total number of workers and the total amount of publication, although this is perhaps the most probable situation if there is no information to the contrary. It seems that England and ancient Greece have produced more than their share of the greatest men and this was indeed found to be the case in my study of the eminent men in the world's history.³ It may be that at the present time Holland with 12 physicists attributed to it is making more

³ "A Statistical Study of Eminent Men," *The Popular Science Monthly*, February, 1903.

important contributions to that science than the United States with 131. In psychology, which is the only subject on which I can speak with adequate information, we appear to lead in importance as well as in quantity of work.

In the last two columns of the table are given the numbers of scientific men in proportion to the populations of the different countries. The first column gives the numbers per million in 1860, which was about the average time at which they were born; the second column gives the numbers in relation to the present populations. In France, with a nearly stationary population, the figures in the two columns are of course nearly the same. In the United States and the British Dominions, with rapidly increasing populations, the proportion is much smaller in relation to the existing population than to the birth rate. For a given stock and civilization, if scientific productivity were wholly due to the innate constitution of the individual, the numbers should be proportional to the population at the time of their birth; if wholly due to opportunity it should be proportional to the existing population. An adequate study might contribute toward the solution of this problem.

Taking either the one figure or the other in the table, it is obvious that while in total productivity we may surpass every other nation, this is far from being the case in proportion to our population. This situation is still less creditable to us when wealth and opportunities for higher education are taken into consideration. It should, however, be noted that the lower figures can be attributed in part to the large Negro and immigrant populations and to an unproductive South. Our scientific men appear now to be increasing about four times as rapidly as the population, and the figures in the table have for this and other reasons (including redistribution of populations after the war) only a limited application. When allowance is made for disturbing factors, the number of scientific men of standing in proportion to the present population appears to be nearly the same in the United States, Great Britain and Germany, about half as large in France and a quarter as large in

Italy. Norway and Switzerland have by far the largest proportion, followed among the smaller nations by Denmark, Holland and Sweden. I should have expected Holland to stand first, and it may, for the figures collected from the book have inconsiderable validity.

The greater relative productivity of the smaller cultural nations in science—the same situation probably holding in literature and in art—is a matter of considerable interest. It goes back to the Greek democracies and to the Italian states of the renaissance. In this country we had a local development in Massachusetts and Connecticut, in which, according to my statistics, the birth rate per million population of scientific men more highly selected than those on the international list was 109 and 87, respectively. If these figures are increased to make up for the number of scientific men given in the table, they become, respectively, 201 and 160, a much larger birth rate of scientific men than that of any foreign nation. It is probable that a similar situation now holds in California and in parts of the central west.

We apparently need regional cultivation of special fields with a group and a community interest in the work. The situation is difficult, for with the increasing complexity of science and in our existing competitive system there must be support of research through taxation or gifts. But control from Washington, whether by the national government, or by a group of men who administer philanthropic funds, may do more to suppress research than to forward it, the rarer flowers of genius being particularly apt to wither when frost and sunlight are artificially controlled.

We are so ignorant of the causes of scientific productivity that it is possible for Galton to attribute it almost wholly to heredity in superior lines of descent, for Odin to claim that genius is in things, not in men. Yet it is a subject of fundamental importance both from the point of view of constructive science and for the applications of science to human welfare. The field is nearly untilled and for that very reason may prove to be fertile.
